

HOMEWORK: HOMEWORK 4.2

Now convert the mongod instance (the one in the problem 4.1 above, which uses “--dbpath 1”) to a single server replica set. To do this, you’ll need to stop the mongod (NOT the mongo shell instance) and restart it with “--replSet” on its command line. Give the set any name you like.

Then go to the mongo shell. Once there, run

```
> rs.initiate()
```

Note: if you do not specify a configuration, the mongod will pick one based on your computer's hostname.

When you first ran homework.init(), we loaded some data into the mongod. You should see it in the replication database. You can confirm with:

```
> use replication
> db.foo.find()
```

Once done with that, run

```
> homework.b()
```

in the mongo shell and enter that result below.
